LAMP HAVING MULTI-FUNCTIONAL SUPPORT

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation-in part of and claims the benefit of U.S. patent application Ser. No. 13/837,744, filed Mar. 15, 2013, the contents of which are incorporated herein by reference in their entirety.

This application also claims the benefit of Chinese Utility Model Patent Application No. 201320267515.9, filed May 16, 2013, and the benefit of Chinese Utility Model Patent Application No. 201320801772.6, filed Dec. 9, 2013, the contents of both of which are incorporated herein by reference in their entirety.

TECHNICAL FIELD

This relates to lamps, and more particularly, to lamps having multi-functional supports.

BACKGROUND

A table lamp typically has a support body for supporting and mounting various components of the lamp. Lamp support bodies may also be shaped, or formed of different articles, for decorative or artistic purposes. For example, lamp support bodies have been shaped like basketballs, or formed using a bottle or baseballs.

SUMMARY

In an aspect, there is provided a lamp including a support and a socket on the support for receiving a light bulb and selectively providing power thereto. The support has a body portion shaped to resemble a selected article. The body portion has a cavity or recess shaped to form an indicia indicating an entity associated with the selected article. The cavity or recess is positioned to receive light from the light bulb, and is filled with a photoluminescent material.

In another aspect, there is provided a method that includes identifying an article for conveying a message, for promoting the article, or for promoting an entity associated with the article. The method also includes obtaining or forming lamps, which may each be a lamp as disclosed herein. The body portion of each lamp is shaped to resemble the identified article and the indicia on the body portion indicates the entity associated with the article. The method may also include distributing the lamps for viewing by members of a target group to convey the message to the members, or to promote the selected article to the members, or to promote the entity associated with the article to the members.

In a further aspect, there is provided a method comprising identifying an article and an associated entity to be promoted, and distributing lamps to members of a target group. The body portion of each lamp may resemble the identified article, and the indicia on the body portion may indicate the identified associated entity. Each lamp may be a lamp as disclosed herein.

In yet further aspects, a lamp as disclosed herein is used for conveying a message, for promoting a selected article, for promoting an entity associated with the selected article, or for promoting a product marketed by the entity, wherein the selected article represents the product.

In yet another aspect, there is provided a lamp having a support and a socket on the support for receiving a light bulb

2

and selectively providing power thereto. The support includes a body portion having a cavity or recess shaped to form an indicia. The cavity or recess is positioned to receive light from the light bulb and is filled with a photoluminescent material.

In another aspect, there is provided a method of forming a lamp support. The method includes providing a lamp support comprising a body portion shaped to resemble a selected article, the body portion having a cavity or recess shaped to form an indicia indicating an entity associated with the selected article, and filling the cavity or recess with a photoluminescent material. Filling the cavity or recess may include binding the photoluminescent material to the body portion in the cavity or recess, or sealing the photoluminescent material in the cavity or recess.

BRIEF DESCRIPTION OF THE DRAWINGS

In the figures which illustrate example embodiments,

FIG. 1A is a side elevation view of a lamp, exemplary of an embodiment;

FIG. 1B is side elevation view of the lamp of FIG. 1A, with a lampshade;

FIG. 2A is a cross-sectional view of the lamp of FIG. 1A, taken along line 2-2;

FIG. 2B is a partial cross-sectional view of a lamp body, exemplary of another embodiment;

FIG. 2C is a partial cross-sectional view of a lamp body, exemplary of a further embodiment;

FIG. 3 is a side elevation view of a lamp body, exemplary of another embodiment;

FIG. 4 is a side elevation view of a lamp body, exemplary of a further embodiment;

FIG. 5 is a side elevation view of a lamp body, exemplary of yet another embodiment; and

FIG. 6 is a side elevation view of a lamp body, exemplary of a yet further embodiment.

DETAILED DESCRIPTION

It has been recognized that lamps, particularly lamp support bodies, can be used to perform multiple functions. For example, a lamp disclosed herein may also be conveniently used to promote a product, an entity, or association between the product and the entity. Thus, a lamp support body disclosed herein may be conveniently used to convey a message or information, in addition to supporting other lamp components and being decorative. It has also been recognized that an embodiment disclosed herein may better perform such an additional function.

FIGS. 1A and 1B depict a lamp **100**, exemplary of an embodiment. As depicted in FIG. 1A, lamp **100** includes a support **102** comprising a base **103** and a body **104**. As depicted in FIG. 1B, lamp **100** may also include a removable lampshade **114**. A socket **106** is provided on the top end of support **102** for receiving a light bulb, e.g., light bulb **108**, and selectively providing power to that light bulb. Body **104** is shaped to resemble a selected article, e.g., a bottle as depicted, and includes recesses **132** shaped to provide indicia **130** indicating an entity associated with the selected article. Recesses **132** are positioned to receive light from a light bulb received in socket **106**, and are filled with a photoluminescent material, causing indicia **130** to be photoluminescent. When the light bulb is on, the photoluminescent material absorbs light from the light bulb and emits light in response. The photoluminescent material may be an afterglow material so it glows for an extended period of time after the light bulb has been turned

off. The light emitted by the photoluminescent material allows indicia **130** to be seen even in the dark.

The shape of body **104** and photoluminescent indicia **130** provided thereon cooperate to convey a message or information to individuals who are looking at lamp **100**, including when lamp **100** is turned off and is in a dark environment. Thus, lamp **100** may be conveniently used as a medium for disseminating a message or information. For example, lamp **100** may be used to promote the selected article that body **104** is shaped to resemble, or its associated entity, as indicated by photoluminescent indicia **130**.

Base **103** includes a substantially flat bottom surface allowing lamp **100** to be rested on a substantially flat surface, and is sized and weighted to stabilize lamp **100**. As depicted, base **103** is substantially cylindrical in shape. However, in other embodiments, base **103** may be shaped like a prism, a pyramid, a cone, a half-sphere, or the like. In the depicted embodiment, base **103** is made of metal. However, base **103** may also be made of another type of material such as rock, ceramic, wood, plastic, or combinations thereof. Other types of suitable materials will be apparent to those of ordinary skill in the art. For ease of manufacture, base **103** may be formed from the same material(s) as body **104**, as detailed below. Base **103** includes a switch **112** for controlling the supply of electric power to light bulb **108**, further detailed below.

Body **104** is mounted on base **103**, and elevates socket **106**, light bulb **108**, and lampshade **114** from base **103**. Body **104** may be securely fastened to base **103** using conventional fasteners such as adhesives, screws, bolts, ties, or the like. Body **104** may be made of materials that are strong enough to support socket **106**, light bulb **108**, and lampshade **114**, while also being sufficiently workable to allow body **104** to be readily shaped. For example, in the depicted embodiment, body **104** may be made of rock, specifically, marble. Body **104** may also be made of another type of rock such as granite, limestone, a gemstone (e.g., jade, malachite, quartz), or the like. Body **104** may also be made of other materials such as ceramic, crystal, glass, cast stone, plastic, synthetic resin, wood, metal (e.g., copper, brass, or steel), or the like. As will be appreciated, when body **104** is made of a transparent or translucent material (e.g., crystal, glass, or translucent ceramic), body **104** may be transparent or translucent.

As noted, body **104** is shaped to resemble a selected article. Body **104** may be shaped to resemble any selected article having a recognizable shape. In particular, body **104** may be shaped to resemble a selected article for which it is desirable to convey some information or message to users of lamp **100**, or to others that might view lamp **100**. For example, body **104** may be shaped to resemble a consumer product to convey notice of that consumer product to consumers, and thereby promote it. For example, as depicted in FIGS. 1A and 1B, body **104** may be shaped like a wine bottle. Other example shapes are depicted in FIGS. 3, 4, 5 and 6 further discussed below.

Body **104** may be formed into a given shape (e.g., resembling a selected article) using conventional sculpting processes. As will be appreciated, suitable sculpting processes may depend on the material of body **104**. For example, body **104** may be shaped by cutting, carving, or drilling, or the like, e.g., when body **104** is made of rock or wood. Body **104** may also be shaped using a casting process and an appropriate mold, e.g., when body **104** is made of ceramic, plastic, or metal. For example, when body **104** is made of metal, body **104** may also be shaped using a combination of bending, pressing, stamping, or forging processes. When body **104** is made of ceramic, body **104** may be formed by sintering.

Body **104** may be colored to match the color(s) of the selected article. For example, the material of body **104** may be chosen to match the colors of the selected article. Further, coloring agents may be introduced during the manufacturing process of body **104** to set its color.

Body **104** may have an outer wall **118** defining and substantially enclosing a hollow interior **116** (FIG. 2A). The thickness of outer wall **118** is selected to be sufficient to allow recesses of sufficient depth to be provided thereon or cavities of sufficient depth to be provided therein, as detailed below. At the same time, the thickness of outer wall **118** is selected to define hollow interior **116** of sufficient size to allow a cord **110** to pass therethrough, for connecting socket **106** to a power supply through switch **112**. In some embodiments, the thickness of outer wall **118** may be selected to define hollow interior **116** of sufficient size to house other objects, which are detailed below. Outer wall **118** may provide an outer surface **120** that is substantially smooth. In some embodiments, outer surface **120** may be glossy. As will be appreciated, when body **104** is made of a transparent or translucent material, the contents in interior **116** may be visible through outer wall **118**.

In the depicted embodiment, outer surface **120** includes recesses **132** shaped to form indicia **130**. As noted, body **104** may be shaped to resemble a selected article. Correspondingly, recesses **132** may be shaped such that indicia **130** indicates an entity associated with the selected article. In this way, the shape of body **104** conveys notice of the selected article, while indicia **130** conveys notice of an entity associated with the selected article. Further, the shape of body **104** and indicia **130** cooperate to convey notice of the association between the entity and the selected article, which may establish or reinforce that association in the minds of individuals who view lamp **100**.

In some embodiments, the selected article may be a consumer product, and indicia **130** may indicate a business associated with that consumer product, e.g., a manufacturer, retailer, or distributor of that consumer product. Thus, the entity indicated by indicia **130** may be a trade-mark, trade-name, or brand-name used by that business. In such embodiments, body **104** and indicia **130** cooperate to convey notice of the association between the consumer product and the business. Thus, lamp **100** may be used by a business as a medium for disseminating a commercial message, e.g., to advertise the business entity's product or otherwise encourage consumers to purchase that product, as further detailed below. For example, in the depicted embodiment, body **104** is shaped to resemble a wine bottle, while indicia **130** indicates "ABC", which may be a brand-name used by a business associated with that bottle of wine, e.g., a manufacturer, retailer, or distributor of that bottle of wine. Lamp **100** may be thus be used by that business to promote its wine product.

As depicted, indicia **130** includes only text. However, in other embodiments, recesses **132** may form indicia including any one or a combination of text, symbols, logos, designs, graphics, or the like. As will be appreciated, the number of recesses **132** may vary depending on the indicia to be formed. For example, in some embodiments, indicia may be formed using only a single recess **132**.

Recesses **132** may be formed using a variety of conventional processes. Recesses **132** may be formed by engraving surface **120** using a tool. For example, surface **120** may be engraved manually, or automatically using a computer-controlled tool such as a computer numerical control (CNC) system. Recesses **132** may also be formed using corresponding protrusions on a mold used to form body **104**, e.g., when body **104** is formed using a casting process. Recesses **132**

5

may also be formed using a physical or chemical etching process, e.g., by selectively exposing portions of surface **132** corresponding to the shape of indicia **130** to etchants. Recesses **132** may also be formed by pressing surface **120**. As will be appreciated, suitable processes for forming the recesses **132** may depend on the size, shape, and material of body **104**.

In the depicted embodiment, indicia **130** is formed by recesses **132** on outer surface **120** of outer wall **118**. However, when outer wall **118** is made of a transparent or translucent material, indicia **130** may also be formed, alternatively or additionally, by recesses on an inner surface **122** (FIG. 2A) of outer wall **118**. Indicia may also be formed on objects placed inside hollow interior **116**.

Further, when outer wall **118** is made of a transparent or translucent material, indicia **130** may be outlined by substantially enclosed cavities in body **104** instead of recesses on a surface of body **104**. For example, in an embodiment depicted in FIG. 2C, recesses **132** may be replaced by cavities **132'** in body **104**, e.g., in outer wall **118**, and cavities **132'** are shaped to form indicia **130**. Cavities **132'** may be formed in outer wall **118** using conventional processes, e.g., by cutting, carving, or drilling into outer wall **118**. Cavities **132'** may also be formed in outer wall **118** using a casting process and an appropriate mold.

As detailed below, recesses **132** or cavities **132'** defining indicia **130** are filled with the photoluminescent material. Thus, indicia **130** may be seen even in the dark, and notice of the entity indicated by indicia **130** continues to be conveyed for a period of time even after lamp **100** is turned off and the environment is dark.

To allow the photoluminescent material in recesses **132** or cavities **132'** to absorb light from light bulb **108**, recesses **132** and cavities **132'** are positioned on body **104** to receive light from light bulb **108**. Such light may be received directly from light bulb **108**, or indirectly by reflection. Directly receiving light from light bulb **108** may allow indicia **130** to glow longer and more brightly in the dark.

Further, in embodiments of lamp **100** to be used as a medium for disseminating a message or information, such as for a promotional purpose, recesses **132** and cavities **132'** may be positioned on body **104** in a prominently visible location, e.g., centrally on body **104**, to attract viewer attention. Similarly, recesses **132** or cavities **132'** may be sized to form indicia **130** of a prominently visible size such that indicia **140** may be seen even from a distance. Forming indicia **130** to be prominently visible may allow indicia **130** to convey information more effectively. In some embodiments, indicia **130** may be placed and sized to resemble actual indicia borne on the selected article that body **104** is shaped to resemble. Placing and sizing indicia **130** to resemble actual indicia on the selected article may enhance the resemblance between body **104** and the selected article.

In some embodiments, the bottom end of body **104** may be adapted to provide a stable support for lamp **100** such that base **103** may be omitted from support **102**. In such embodiments, switch **112** may be moved to another location on lamp **100**, e.g., on body **104**, or on socket **106**, or provided on a power cord connected to socket **106**. In other embodiments, base **103** and body **104** may be formed as a unitary piece. For example, base **103** and body **104** may be formed from a single piece of rock, or using a single mold during a casting process.

Socket **106** is provided on the top end of body **104** and is adapted to receive light bulb **108** and to selectively provide power thereto. Socket **106** may be mounted to the top end of body **104**, using conventional mounting techniques. For example, the bottom end of socket **106** may include a lip

6

extending downwardly around its perimeter to define a cavity sized to receive and retain the top end of body **104**. Alternatively, socket **106** may simply be placed on top of body **104** and securely fastened thereto. Socket **106** may be securely fastened to body **104** using conventional fasteners, such as, e.g., adhesives, screws, bolts, ties, or the like. Socket **106** may be made of ceramic, plastic, metal, or another suitable material. Socket **106** includes metal connectors for electrical connection with light bulb **108**. In some embodiments, lamp **100** may include additional sockets for receiving additional light bulbs.

As depicted, light bulb **108** is a conventional incandescent bulb. In other embodiments, light bulb **108** may be a halogen bulb, a fluorescent bulb, a compact fluorescent bulb, a high-intensity discharge (HID) bulb, a light-emitting diode (LED), or the like. In some embodiments, light bulb **108** may be replaced with an array of light bulbs in one or more sockets, connected in a variety of series and/or parallel arrangements.

Light bulb **108** may include a conventional Edison screw base for engaging complementary screw threads on the interior surface of socket **106**. In other embodiments, light bulb **108** may be coupled to socket **106** using another type of connection such as a bayonet connection or bi-pin connection. Other types of connections may also be used.

When light bulb **108** is received within socket **106**, electrical terminals in the base of light bulb **108** are in electrical communication with corresponding terminals within socket **106**. In turn, terminals of socket **106** may be electrically connected to mains power by way of a power cord **110**. As depicted, power cord **110** extends through hollow interior **116** (FIG. 2A) of lamp body **104**, and through base **103**. Alternatively, power cord **110** may extend on the outside of body **104**, e.g., when body **104** is not hollow. Power cord **110** is connected to switch **112**, which allows the supply of power to be controlled, and thereby selectively turn light bulb **108** on or off. Power cord **110** is terminated outside of lamp **100** by a conventional plug for connection with mains power. In another embodiment, socket **106** may be connected to one or more batteries that allow light bulb **108** to be operated under battery power. Such batteries may be located or housed inside lamp **100** (e.g., within body **104** or base **103**), or outside lamp **100**.

Switch **112** is used to control the supply of power to light bulb **108**. As depicted, switch **112** is mounted on base **103**. In the depicted embodiment, switch **112** is a rocker switch, allowing light bulb **108** to be selectively toggled between on and off conditions. In other embodiments, switch **112** may be another type of switch such as, e.g., a pole switch, a rotary switch, a dimmer switch, a push-button switch, or a solid state switch. The switch may further include, for example, a control circuit for enabling the switch to function as a multi-stage switch, such that multiple light bulbs may be independently controlled by the same switch.

As depicted in FIG. 1B, lamp **100** may include a removable lampshade **114** that diffuses light passing through it, such as light emitted by light bulb **108**. As depicted, lampshade **114** is substantially frustoconical in shape. However, in other embodiments, lampshade **114** may have a different shape; for example, lampshade **114** may be shaped as a cylinder, a prism, a pyramid, or the like. In the depicted embodiment, lampshade **114** is made of fabric. However, in other embodiments, lampshade **114** may be made from other materials such as, e.g., paper, glass, ceramic, or the like. Lampshade **114** includes a support frame that is mountable to the socket **106**. Lampshade **114** may be securely fastened to socket **106** using conventional fasteners.

The photoluminescent indicia **130** provided on body **104** of lamp **100** is further described with reference to FIG. 2A, which is a cross-sectional view of body **104** along line 2-2 of FIG. 1A. Each recess **132** may extend into body **104** to a depth *d* (FIG. 2A) of approximately 2 mm. In some embodiments, this depth may vary between approximately 0.5 mm to approximately 10 mm.

As will be appreciated, providing recesses **132** filled with the photoluminescent material allows the photoluminescent material to be applied to body **104** in a thicker layer, as compared to applying the photoluminescent material simply as a surface coating on body **104** (e.g., when the photoluminescent material is printed on body **104**). This in turn allows photoluminescent indicia **130** to emit light more brightly and to be visible for a longer duration in the dark. Further, providing recesses **132** and controlling their depths allows the amount of photoluminescent material that may be contained in recess **132** to be controlled. This allows the brightness and duration of afterglow to be controlled. As a larger amount of the photoluminescent material may be used to obtain the desired brightness and duration, a wider selection of photoluminescent materials may be used. In comparison, for a thin surface coating to be sufficiently bright, suitable photoluminescent materials are more limited, as materials that exhibit weaker photoluminescent emission intensity may not be useful.

As depicted, each recess **132** is filled with a photoluminescent material to form photoluminescent layer **134**. The photoluminescent material in photoluminescent layer **134** may be a phosphorescent material, and may include a fluorescent material. Conveniently, unlike fluorescence, phosphorescence can occur slowly, and some phosphorescent materials may continue to emit light over a relatively long period of time after absorption of the excitation light. For example, a phosphorescent material may continue to emit light hours after absorption of the excitation light. On the other hand, a fluorescent material may conveniently emit more intense light when excited than a phosphorescent material. A photoluminescent material may absorb incident light having a first wavelength and emit light at a second wavelength different from the first wavelength.

Depending on the particular application, suitable phosphorescent materials may include sulfides such as zinc sulfide or calcium sulfide, alkaline earth aluminates (e.g., alkaline earth aluminate oxides such as strontium aluminum oxides, calcium aluminum oxides, or barium aluminum oxides), alkaline earth silicates, rare earth metals or rare earth oxides, and combinations thereof. As is known, the phosphorescent material may include impurities or a dopant as an activator. An activator that may be included in the phosphorescent material can be used to adjust the color (i.e., wavelength) of the light emitted and the emission duration. For example, the phosphorescent material may be formed by combining zinc sulfide with a copper activator. Other metal activators that may be used in different embodiments include aluminum, cobalt, silver, gold, manganese, gallium, indium, scandium, lead, cerium, terbium, europium, gadolinium, samarium, praseodymium, and other rare earth elements. Halogens may also be used as activators. Other suitable phosphorescent or afterglow materials known to those of ordinary skill in the art may also be used.

In some embodiments, the photoluminescent material in photoluminescent layer **134** may be formed by mixing a suitable photoluminescent powder with a suitable liquid including a binder that binds the powder together as well as to a surface (e.g., a surface of recess **132**) when cured. Suitable powder and binder materials may be obtained from commercial

sources. For example, in one specific embodiment, the powder is phosphorescent powder TD-4A, provided by Shiyatu Chemical Industry (Shenzhen, China), and the liquid is obtained by mixing a clear varnish and a diluent, both provided by Foshan Yingcai Paint Products Co., Ltd. (Foshan, China). In this specific embodiment, the varnish and diluent are mixed in a 1:1.5 ratio. Bright and long lasting phosphorescent materials may also be formed from Europium Ultra-Glow™ powders, provided by United Nuclear Scientific LLC (East Lansing, Mich., USA).

During manufacture of lamp **100**, photoluminescent layer **134** in each recess **132** may be formed using a conventional technique. For example, the photoluminescent material may be deposited in each recess **132** in the form of a liquid, gel, or resin, and allowed to dry and harden therein to form photoluminescent layer **134**. In the depicted embodiment, photoluminescent layer **134** is formed to substantially fill a recess **132**, so that its top surface is substantially flush with outer surface **120** of body **104** (FIG. 2A). In other embodiments, as depicted in FIG. 2B, a recess **132** may be replaced with a recess **132'** that is only partially filled with the photoluminescent material to form a photoluminescent layer **134'** that does not extend the full depth of recess **132'**. In such embodiments, the remaining space in recess **132** may be filled with a protective material to cover photoluminescent layer **134'**, as described below.

Optionally, before the photoluminescent material is applied to recesses **132**, portions of the surfaces of recesses **132** that will contact photoluminescent layer **134** may be primed to improve adherence of photoluminescent layer **134** to the surfaces of recesses **132**. For example, these portions may be primed by roughing the surface using a chemical or physical treatment, or by applying a primer coating. In some embodiments, photoluminescent layer **134** may include other materials such as a binder or adhesive to adhere photoluminescent layer **134** to recesses **132**.

In some embodiments, photoluminescent layer **134** may be transparent or semi-transparent. For example, this may allow interior **116** of body **104** to be visible through photoluminescent layer **134**. This may also allow the photoluminescent layer **134** (and indicia **130**) to remain relatively invisible when it is not emitting visible light.

As noted, in some embodiments, recesses **132** may be replaced by cavities **132"** (FIG. 2C). As shown in FIG. 2C, in such embodiments, a photoluminescent layer **134"** is formed within a cavity **132"**. Photoluminescent layer **134"** may be formed by filling a cavity **132"** with a photoluminescent material. For example, a photoluminescent material in the form of a liquid, gel, resin, or powder may be introduced (e.g., injected or poured) into a cavity **132"** by apertures (not shown), each connecting a cavity **132"** with the exterior of body **104**. In some embodiments, e.g., when the photoluminescent material is a resin, the photoluminescent material may be cured in cavity **132"**, and once hardened, be retained within cavity **132"**. In such embodiments, the apertures connected to cavities **132"** may be left unsealed. In other embodiments, the apertures may be sealed after cavities **132"** are filled with the photoluminescent material, e.g., by applying a coating to the surface of body **104** such as a protective coating as described below.

Cavities **132"** may be formed to have a depth *d'* (FIG. 2C) similar to depth *d* of recesses **132**. As such, depth *d'* may be approximately 2 mm, and may vary between approximately 0.5 mm to approximately 10 mm. Like recesses **132**, cavities **132"** allow the photoluminescent material to be provided in a thicker layer than when the photoluminescent material is simply applied as a coating on body **104**. Further, controlling

the depth d' of cavities **132**" allows the amount of the photoluminescent material in cavities **132**", and correspondingly the brightness and duration of afterglow to be controlled.

Conveniently, providing the photoluminescent material in a recesses or a cavity reduces or prevents the incidence of physical contact with that photoluminescent material, e.g., when lamp **100** is cleaned or handled, and thereby protects the photoluminescent material from damage or unintentional removal caused by such contact.

Optionally, when the photoluminescent material is contained in recesses on the surface of body **104**, the photoluminescent material may be further protected by applying a clear protective coating over it. For example, as depicted in FIG. 2A, protective material may be applied to body **104** to form a protective coating **136**. Protective coating **136** acts as a barrier protecting photoluminescent layer **134** from damage or unintentional removal due to physical contact. In some embodiments, protective coating **136** may also protect photoluminescent layer **134** from damage caused by exposure to one or more of air, moisture, and light (e.g., ultra-violet light). The protective material forming protective coating **136** may, for example, be a varnish, enamel paint, or a clear coat material typically used in the automotive industry. The protective material may contain polyurethanes, urethanes, acrylics, or the like.

Suitable protective coating materials may be obtained from commercial sources. For example, in one specific embodiment, the protective material may be a UV-curable varnish that adheres to rock material, provided by Chengdu Fibrow Composite Materials Technology Co., Ltd. (Chengdu, China). Upon being applied to outer surface **120**, this varnish may be cured at room temperature by UV light to form a protective coating having a pencil hardness rating of at least 3H.

In some embodiments, protective coating **136** may be formed to substantially cover outer surface **120** of body **104**, and in this way also protect outer surface **120**. Conveniently, protective coating **136** may provide outer surface **120** with a glossy finish. In other embodiments, protective coating **136** may be formed to cover only part of outer surface **120**, e.g., only a region or regions containing recesses **132**. For example, it may be desirable to cover only those regions containing recesses **132** with protective coating **136** to retain the natural finish of outer surface **120** in other regions.

In yet other embodiments, as depicted in FIG. 2B, a protective material may be applied within recesses containing photoluminescent material. For example, a protective material may be applied in each recess **132** to form a protective coating **136'** over each photoluminescent layer **134'**. As depicted, protective coating **136'** may be formed to be substantially flush with outer surface **120**. Protective coating **136'** may have a similar finish as outer surface **120** (e.g., smooth and/or glossy), such that protective layer **134'** is not visually distinctive relative to outer surface **120**.

In some embodiments, protective coating **136** or protective coating **136'** may be a multi-layer coating. For example, a multi-layer coating may include a primer or a base coat, and a top coat.

During operation of lamp **100**, power cord **110** can be plugged into mains power to provide an electrical connection to light bulb **108**. Light bulb **108** can be turned on by operating switch **112**, causing light bulb **108** to emit light. Photoluminescent indicia **130** absorbs light emitted from light bulb **108**, and may also absorb light from other sources (e.g., room lights or ambient light). In response to absorbing light, the photoluminescent material emits light, causing indicia **130** to glow even long after light bulb **108** has been turned off. For

example, when the photoluminescent material is a suitable phosphorescent material, indicia **130** may continue to glow for hours after light bulb **108** has been turned off. Light emitted by photoluminescent indicia **130** may not be apparent to users when light bulb **108** is turned on or the environment is bright. However, when light bulb **108** is turned off and the environment is dark, light emitted by photoluminescent indicia **130** will be readily apparent.

Thus, indicia **130** may be seen for an extended period of time after light bulb **108** has been turned off and the environment is dark. In some embodiments, e.g., when the photoluminescent material is transparent, indicia **130** may become noticeable for a period of time only after light bulb **108** has been turned off and the environment is dark.

FIGS. 3, 4, 5 and 6 depict alternate embodiments of the body of lamp **100**.

In particular, FIG. 3 depicts a body **204** shaped to resemble a basketball. As depicted, the outer surface of body **204** includes recesses defining indicia **230**, namely, "Team XYZ", i.e., indicating the name of a basketball team. Thus, a lamp **100** having body **204** conveys information regarding an association between Team XYZ and basketball, and may be used to promote Team XYZ, such as prompting individuals to watch basketball games played by Team XYZ. The information conveyed by lamp **100** having body **204** may make such a lamp desirable to some consumers (e.g., fans of Team XYZ) for its value as a collectible object or memorabilia.

FIG. 4 depicts a body **304** shaped to resemble a bottle of pills. As depicted, the outer surface of body **304** includes recesses defining indicia **330**, namely, "A1 Limited", i.e., indicating a manufacturer of the pills. Thus, a lamp **100** having body **304** may be used to promote pills made by A1 Limited. As depicted, body **304** includes a translucent outer wall allowing the interior of body **304** to be visible through the outer wall. As depicted, objects resembling pills may be placed within the interior of body **304** to be visible through the outer wall. Such objects may be formed from materials similar to the materials used to form body **304**, as discussed above, or other suitable materials.

FIG. 5 depicts a body **404** shaped to resemble four basketballs stacked vertically. In particular, body **404** is shaped to resemble four basketballs stacked vertically, with the bottom-most basketball being larger than the other three basketballs, which are of substantially the same size. The outer surface of body **404** includes recesses defining indicia **430A**, **430B**, **430C**, and **430D** that may indicate the name of an entity associated with basketballs (e.g., a basketball team), or a logo of such an entity (e.g., a logo shaped like a star, as indicated by indicia **430D**). Thus, like a lamp having body **204**, a lamp having body **404** may be used to promote a basketball team.

FIG. 6 depicts a body **504** shaped to resemble four basketballs stacked vertically on a half-basketball. As depicted, the half-basketball is larger than the other four basketballs, which are of substantially the same size. Body **504** has a substantially flat bottom surface (i.e., the bottom surface of the half-basketball) that allows body **504** to support lamp components on a substantially flat surface. As such, a lamp **100** having a body **504** need not include a separate base. The outer surface of body **504** includes recesses defining indicia **530A**, **530B**, **530C**, **530D**, and **530E** that may indicate the name of an entity associated with basketballs (e.g., a basketball team), or a logo of such an entity (e.g., a logo shaped like a sun, as indicated by indicia **530E**). Like a lamp having body **204** or **404**, a lamp having body **504** may also be used to promote a basketball team.

11

As will be appreciated, the height of body **404** or **504** may be adjusted by changing the shape of body **404** or **504** to resemble a fewer or greater number of basketballs.

The recesses on body **204**, **304**, **404**, or **504** may be filled with a photoluminescent material, as for body **104**.

As now can be appreciated, the body material for the lamps may be selected based a number of factors. For example, the body material may need to be sufficiently strong to support the lamp components to be supported and mounted thereon. Further, the body material may be selected based on workability for ease of production. In particular, the body material should be suitable for forming recesses and cavities as described herein, and be compatible with the photoluminescent material and the manufacturing processes to be used for forming the recesses and cavities and any coatings on the support body. The body material may also be selected to suit the target group's tastes. For example, while marble can be readily shaped into a desired shape and to form a recess for holding a photoluminescent material, marble is also considered to be a desirable luxury material for some consumers.

The photoluminescent material filled in recesses or cavities on the support body may also be selected based on a number of factors. For example, the photoluminescent material may be selected based on the rate at which the material emits light after absorbing excitation light. As noted, it may be desirable in embodiments to select a photoluminescent material that is phosphorescent and has a relatively slow emission rate and thus a relatively long emission lifetime when excited (long-lasting afterglow). In some embodiments, this lifetime may be up to several minutes or several hours, and may, for example, be over ten minutes. In other embodiments, this lifetime may be even longer, e.g., over ten hours. The photoluminescent material may also be selected based on the intensity of the light emitted. As noted, the intensity of the light emitted and the duration the light is visible in the dark may also depend on the quantity of the photoluminescent material used, which may be controlled by controlling the depth of recesses or cavities provided on the support bodies for containing the photoluminescent material. The photoluminescent material may also be selected based on the wavelengths of the light required for excitation. In particular, the required excitation wavelengths should include wavelengths emitted by the light bulb of the lamp. The photoluminescent material may also be selected based on the wavelengths of the light emitted after excitation. In particular, the emitted wavelengths should include visible light. Further, the emitted wavelengths may be controlled such that the color of the emitted light is a desired color. The photoluminescent material may also be selected for its compatibility with the body material, any binders or adhesives that may be required to adhere the photoluminescent material to the body material, any protective coating applied over the photoluminescent material, and its suitability for forming into a liquid, gel or resin, as may be necessary to apply the photoluminescent material to lamp support bodies during the manufacturing of the lamps.

The material of the protective coating applied over the photoluminescent material may also be selected based on a number of factors. For example, the protective coating may be selected based on its hardness and ability to protect the photoluminescent material from damage or unintentional removal due to physical contact. In an embodiment, the protective coating may have a hardness rating greater than 3H. The protective coating may also be selected based on its suitability to protect the photoluminescent material from damage caused by exposure to one or more of air, moisture, and light (e.g., ultra-violet light). The protective material may

12

also be selected based on other factors, such as the thickness of the protective coating provided, the durability of the coating, the transparency of the coating, and the smoothness or glossiness of the finish provided by the coating, and its compatibility with the body material and the photoluminescent material.

As noted, lamp support bodies may serve a function in addition to supporting other lamp components and being decorative. For example, as disclosed herein, lamp support bodies may also be used to convey a message or information. As such, lamps having suitable support bodies may be used to disseminate a particular message or particular information, when formed and distributed to be viewed by targeted recipients of that message or information. For example, lamps having suitable support bodies may be used to disseminate a message regarding a selected article, an entity associated with that article, or an association between the entity and the selected article. Thus, the lamps may be used to promote the article, the entity, and/or the association therebetween. For example, then the selected article is a particular product and the associated entity is a business marketing that product, lamps having suitable support bodies may be used to promote the business, the product, or the association between the business and the product.

First, a suitable article is identified or selected. For example, when the lamps are used to disseminate a message promoting a particular product having a defined shape, a suitable article may simply be selected to be that product. Lamps may also be used to promote a particular intangible product without a defined shape, such as a movie or a video game. In this case, a suitable article may be selected to be an article that represents or is uniquely associated with the intangible product, e.g., the selected article may be a recognizable object from the movie or video game. Lamps may also be used to promote a particular intangible product that is a service, a performance, or sporting event. For example, a suitable article may be selected to be a tooth to represent a dentistry service, or a musical note to represent a concert, or a baseball bat to represent a baseball game. Lamps may also be used to promote non-commercial events, such as a wedding, a bar mitzvah, or the like. For example, a suitable article may be selected to be a wedding cake to represent a wedding. Lamps may also be used to disseminate a message promoting a particular organization such as a company, a political organization, a religious organization, an educational institution, or the like. For example, a suitable article may be selected as a cross to represent a Christian organization.

A suitable indicia may also be identified to indicate the entity associated with the selected article. The indicia may simply be the name of the entity. When the selected article is a product, the indicia may be a trade-name, trade-mark, or brand-name used by the entity in association with the selected article.

Next, a plurality of lamps **100** are formed or otherwise obtained. The support body of each of the plurality of lamps is shaped to resemble the selected article, and has an indicia indicating the entity associated with the selected article.

Once formed or obtained, the lamps are distributed to be viewed by members of a target group, namely, intended recipients of the message or information to be disseminated. For example, the target group may be potential customers of a product, potential attendees or participants of an event, or the public at large. The lamps may be distributed to members of the target group. The lamps may also be distributed to establishments or locations where members of the target group are expected to visit. For example, the lamps may be distributed to business establishments, such as stores, malls,

13

restaurants, bars, theatres, or the like. The lamps may also be distributed to other types of establishments and locations such as workplaces, schools, townhalls, or the like. The lamps may also be distributed through various channels of trade, such as stores, websites or the like. When used for a promotional purpose, the lamps may be distributed as promotional materials free-of-cost, or for a nominal cost, e.g., to cover the cost of manufacturing the lamp.

Once distributed, the lamps may function to convey a message or information to individuals who look at the lamps. For example, the lamps may function to promote to those individuals the selected article, a product or event represented by the article, an entity associated with the article, or an association between the entity and the article.

Lamps having support bodies suitable for conveying a message or information may also be used for purposes other than promotion. For example, the lamps may have support bodies that convey a message or information that appeals to certain individuals, such that the lamps may be desirable to those individuals. Lamps may, for example, have support bodies shaped to convey notice of a selected article held in high regard by certain individuals, e.g., an object from a favorite movie or video game. Such lamps may be used as memorabilia. Lamps may also, for example, have support bodies with indicia that conveys notice of an entity held in high regard by certain individuals, e.g., a favorite sports team, a school attended by those individuals, an affiliated religious organization, or an affiliated political party. Lamps may also have support bodies that convey a message or information that entertains certain individuals. For example, the support bodies may have an amusing shape. Similarly, the support bodies may include indicia that conveys a joke or other entertaining message. Such lamps may be sold for profit.

In some embodiments, the entire support body of lamp 100 shaped to resemble a selected article. In other embodiments, a portion of the support body of lamp 100 is shaped to resemble a selected article, and that portion includes a photoluminescent indicia.

Lamp 100 is shown as a table lamp, and is portable and suitable for placing on a flat surface (e.g., a table top). However, in other embodiments, the lamp may be another type, e.g., a floor lamp, a wall-mountable or ceiling-mountable lamp. In yet other embodiments, the lamp may be adapted for exterior use, e.g., including suitable weather protection. For example, in such embodiments, the lamp may be a garden lamp.

In selected embodiments, a lamp may have a body that primarily serves a decorative function in addition to supporting lamp components. In such embodiments, it is not necessary that the support body is shaped to resemble an article to be promoted. For example, the support body may have a common shape for conventional lamp supports (e.g., a sphere, a cone, or a cylinder) or having a decorative shape or a shape for an artistic expression. However, the support body has one or more recesses or cavities filled with a photoluminescent material to form a decorative indicia or artistic expression.

In another embodiment, lamps are used in a method of promotion. The method may be used to promote a particular entity, which may be an entity as discussed above. The method may also be used to promote a product or event that is provided by or is otherwise associated with the particular entity. According to this method, an article is identified for promoting the particular entity or its associated product or event. The article may be identified according to a manner discussed above.

Next, a plurality of lamps are formed or obtained. Each of the lamps has a support body shaped to resemble the identi-

14

fied article. Optionally, the support body may include an indicia, identified according to a manner discussed above. The shape of the support body and the indicia included thereon may, each alone, or in combination, cause the identified article to be recognizable by individuals viewing the lamps.

The lamps may be substantially similar to a lamp 100 described herein. However, the lamps may be another type of lamp with different support bodies. For example, the lamps may have support bodies with an indicia indicating the particular entity provided thereon using a conventional process. For example, the indicia may be painted, printed, carved, or etched on the support bodies, or be applied thereto as a label, sticker or decal. Further, the indicia need not be formed using an afterglow material.

Once the lamps are formed or obtained, they are distributed for viewing by members of a target group to promote the particular entity or to promote its associated product or event to those members. The target group may be a target group as discussed above. The lamps may be distributed according to a manner discussed above.

As used herein, the term "light bulb" is used to broadly refer to any powered light source for use on a lamp. A light bulb may be an incandescent bulb, fluorescent bulb, high-intensity discharge (HID) bulb, a light emitting diode (LED), or the like. The light bulb may also include other light sources suitable for use on a lamp.

As can be appreciated from the description herein, the term "entity" is also used broadly, and can be used to refer to any tangible or intangible object, or any party that can be uniquely identified.

The term "article" is used broadly to refer to any tangible or intangible object or image, or any combination of such objects or images. The term "product" is used broadly to refer to any tangible or intangible product which may include a service (service product) provided by an entity.

It will be understood that the word "a" or "an" is intended to mean "one or more" or "at least one", and any singular form is intended to include plurals herein.

It will further be understood that the term "comprise", including any variation thereof, is intended to be open-ended and means "include, but not limited to," unless otherwise specifically indicated to the contrary.

When a list of items is given herein with an "or" before the last item, any one of the listed items or any suitable combination of two or more of the listed items may be selected and used.

Of course, the above described embodiments are intended to be illustrative only and in no way limiting. The described embodiments are susceptible to many modifications of form, arrangement of parts, details and order of operation. The invention, rather, is intended to encompass all such modification within its scope, as defined by the claims.

What is claimed is:

1. A lamp comprising:

a support comprising a body portion shaped to resemble a selected article, said body portion comprising rock and having a cavity shaped to form an indicia indicating an entity associated with the selected article; and
a socket on said support for receiving a light bulb and selectively providing power thereto;
wherein said cavity is positioned to receive light from said light bulb, and is filled with a photoluminescent material.

2. The lamp of claim 1, wherein said photoluminescent material is phosphorescent.

15

3. The lamp of claim 1, wherein said photoluminescent material comprises a zinc sulfide, a calcium sulfide, an alkaline earth aluminate, an alkaline earth silicate, or a rare earth metal.

4. The lamp of claim 1, wherein said photoluminescent material has an emission lifetime of at least 10 minutes. 5

5. The lamp of claim 1, wherein the article is a product associated with the entity.

6. The lamp of claim 1, wherein the entity is a trade-mark or a trade-name associated with the article, or a business that markets the article. 10

7. The lamp of claim 1, wherein said cavity has a depth between 0.5 mm and 10 mm.

8. The lamp of claim 1, wherein said rock comprises marble, limestone, or granite. 15

9. The lamp of claim 1, wherein said body portion comprises a protective coating covering at least said photoluminescent material.

10. The lamp of claim 9, wherein said protective coating comprises a varnish, an enamel paint, or a clear coat material. 20

11. The lamp of claim 1, wherein said lamp is a table lamp.

12. A method comprising:

identifying an article for conveying a message, for promoting the article, or for promoting an entity associated with the article; 25

obtaining or forming lamps, each being the lamp of claim 1, wherein the body portion of the lamp is shaped to resemble the article, and said indicia on said body portion indicates the entity associated with the article.

16

13. The method of claim 12, further comprising: distributing said lamps for viewing by members of a target group to convey said message to said members, or to promote the selected article to said members, or to promote the entity associated with the article to said members.

14. The method of claim 13, wherein said members are potential customers of the entity associated with the article.

15. The method of claim 13, wherein said distributing comprises distributing said lamps at a businesses establishment visited by said members.

16. The method of claim 13, wherein said distributing comprises distributing said lamps to said members.

17. A lamp comprising:

15 a support comprising a body portion, said body portion comprising rock and having a cavity shaped to form an indicia; and

a socket on said support for receiving a light bulb and selectively providing power thereto;

20 wherein said cavity is positioned to receive light from said light bulb and is filled with a photoluminescent material.

18. The lamp of claim 17, wherein said photoluminescent material is phosphorescent.

19. The lamp of claim 17, wherein said body portion comprises a protective coating covering at least said photoluminescent material. 25

20. The lamp of claim 17, wherein said rock comprises marble, granite, or limestone.

* * * * *
